Chapter 6. Point Estimation Chapter 7. Interval Estimation

Math 3215 Spring 2024

Georgia Institute of Technology

Section 6.3. Order Statistics Order statistics are the observations of the random sample, arranged, or ordered, in magnitude from the smallest to the largest.

Example

The values $x_1 = 0.62$, $x_2 = 0.98$, $x_3 = 0.31$, $x_4 = 0.81$, and $x_5 = 0.53$ are the n = 5 observed values of five independent trials of an experiment with PDF f(x) = 2x for 0 < x < 1.

The observed order statistics are

The sample median is

The sample range is

Let X_1, X_2, X_3, X_4, X_5 be independent random variables with density f(x) = 2x for 0 < x < 1.

Let $Y_1 \leq Y_2 \leq Y_3 \leq Y_4 \leq Y_5$ be the order statistics of X_i , i = 1, 2, 3, 4, 5. What is the distribution of Y_1 ? Let X_1, X_2, X_3, X_4, X_5 be independent random variables with density f(x) = 2x for 0 < x < 1.

Let $Y_1 \leq Y_2 \leq Y_3 \leq Y_4 \leq Y_5$ be the order statistics of X_i , i = 1, 2, 3, 4, 5. What is the distribution of Y_5 ? Let X_1, X_2, X_3, X_4, X_5 be independent random variables with density f(x) = 2x for 0 < x < 1.

Let $Y_1 \leq Y_2 \leq Y_3 \leq Y_4 \leq Y_5$ be the order statistics of X_i , i = 1, 2, 3, 4, 5. What is the distribution of Y_2 ? In general, if $Y_1 < Y_2 < \cdots < Y_n$ are the order statistics of independent random variables X_i for $i = 1, 2, \cdots, n$ with PDF f,

then the distribution of Y_i is

Let X_1, X_2, X_3, X_4, X_5 be independent random variables with density f(x) = 2x for 0 < x < 1.

Let $Y_1 \leq Y_2 \leq Y_3 \leq Y_4 \leq Y_5$ be the order statistics of $X_i, i = 1, 2, 3, 4, 5$. Find $\mathbb{P}(Y_3 \leq 4)$.

Find the density of Y_3 .

Let $Y_1 < Y_2 < \cdots < Y_{19}$ be the order statistics of n = 19 independent observations from the exponential distribution with mean θ .

Find the PDF of Y_1 .

Find $\mathbb{E}[F(Y_1)]$ where F is the CDF of the exponential distribution.

Section 6.4. Maximum Likelihood and Method of Moments Estimation We consider an experiment whose outcome follows a certain distribution.

Assume that the distribution is characterized by a PDF $f(x; \theta)$ where θ is an unknown parameter.

Let Ω be the set of all possible parameters. We call it the parameter space.

Suppose we repeat the *n* independent experiment and observe the outcome (sample) X_1, X_2, \dots, X_n .

Our goal is to estimate θ based on the samples.

Definition

For a function $u : \mathbb{R}^n \to \mathbb{R}$, $u(X_1, X_2, \cdots, X_n)$ is called an estimator (or a point estimator) of θ .

Suppose X_1, X_2, \dots, X_n are independent Bernoulli RVs with unknown success probability $p \in [0, 1]$.

We want to find an estimator of p which maximizes its possibility.

Definition

Let X_1, X_2, \dots, X_n be a random sample from a distribution $f(x; \theta_1, \dots, \theta_m)$, $(\theta_1, \dots, \theta_m) \in \Omega$.

The likelihood function of $\theta_1, \cdots, \theta_m$ is

The maximum likelihood estimators (MLE) of $\theta_1, \cdots, \theta_m$ are

Suppose X_1, X_2, \dots, X_n are independent exponential with mean $\theta \in (0, \infty)$.

Suppose X_1, X_2, \dots, X_n are normal with mean $\theta_1 \in \mathbb{R}$ and variance $\theta_2 \in (0, \infty)$.

Definition

If an estimator $u(X_1, X_2, \dots, X_n)$ of θ satisfies $\mathbb{E}[u(X_1, X_2, \dots, X_n)] = \theta$, we say the estimator is unbiased.

Suppose X_1, X_2, \dots, X_n are normal with mean $\theta_1 \in \mathbb{R}$ and variance $\theta_2 \in (0, \infty)$.

A random sample X_1, X_2, \dots, X_n of size *n* is taken from a Poisson distribution with a mean of $\theta \in (0, \infty)$.

Find the MLE for θ .

Section 7.1. Confidence Intervals for Means Consider a random sample X_1, X_2, \dots, X_n from a normal distribution $N(\mu, \sigma^2)$. We are interested in the closeness of the maximum likelihood estimator \overline{X} to the unknown mean μ .

Suppose σ^2 is known.

Our goal is to find an interval [a, b] such that $\mathbb{P}(\overline{X} \in [a, b]) = 1 - \alpha$, where $\alpha > 0$. Let $z_{\frac{\alpha}{2}} > 0$ be such that $\mathbb{P}(Z \ge z_{\frac{\alpha}{2}}) = \frac{\alpha}{2}$. (Here, Z is standard normal.) Since $(\overline{X} - \mu)/(\sigma/\sqrt{n})$ is standard normal, we have

$$\mathbb{P}\left(-z_{\frac{\alpha}{2}} \leq \frac{\overline{X} - \mu}{\frac{\sigma}{\sqrt{n}}} \leq z_{\frac{\alpha}{2}}\right) = 1 - \alpha.$$

Solving for \overline{X} , we get

$$\mathbb{P}\left(\mu - z_{\frac{\alpha}{2}}\frac{\sigma}{\sqrt{n}} \le \overline{X} \le \mu + z_{\frac{\alpha}{2}}\frac{\sigma}{\sqrt{n}}\right) = 1 - \alpha.$$

Definition

The interval $\left[\mu - z_{\frac{\alpha}{2}} \frac{\sigma}{\sqrt{n}}, \mu + z_{\frac{\alpha}{2}} \frac{\sigma}{\sqrt{n}}\right]$ is called the two-sided confidence interval for unknown μ with confidence coefficient $1 - \alpha$ (for $100(1 - \alpha)\%$).

Let X equal the length of life of a 60-watt light bulb marketed by a certain manufacturer.

Assume that the distribution of X is $N(\mu, 1296)$.

If a random sample of n = 27 bulbs is tested until they burn out, yielding a sample mean of $\overline{X} = 1478$ hours,

then what is a 95% confidence interval for μ ?

If we cannot assume that the distribution from which the sample arose is normal, we can still obtain an approximate confidence interval for μ .

By the central limit theorem, provided that *n* is large enough, the ratio $(\overline{X} - \mu)/(\sigma/\sqrt{n})$ has the approximate normal distribution N(0, 1) even though the underlying distribution is not normal.

Let X equal the amount of orange juice (in grams per day) consumed by an American. Suppose it is known that the standard deviation of X is $\sigma = 96$. An orange growers' association took a random sample of n = 576 Americans and

found that they consumed, on average, $\overline{X} = 133$ grams of orange juice per day.

Even though σ^2 is unknown and the sample distribution is not normal, if *n* is large enought ($n \ge 30$), then

$$rac{\overline{X}-\mu}{rac{S}{\sqrt{n}}}, \qquad S^2=rac{(X-\overline{X})^2}{n-1}$$

is approximately the standard normal.

Thus, a $100(1 - \alpha)\%$ confidence interval is

If the sample distribution is normal, then $\frac{\overline{X}-\mu}{\frac{S}{\sqrt{n}}}$ has a student's *t* distribution with degree of freedom n-1.

Let X equal the amount of butterfat in pounds produced by a typical cow during a 305-day milk production period between her first and second calves.

Assume that the distribution of X is $N(\mu, \sigma^2)$.

To estimate, a farmer measured the butterfat production for n = 20 cows and $\overline{X} = 507.50$ and S = 89.75.

A random sample of size 16 from the normal distribution $N(\mu, 25)$ yielded $\overline{X} = 73.8$. Find a 95% confidence interval for μ .

Section 7.2. Confidence Intervals for the Difference of Two Means Let X_1, X_2, \dots, X_{n_X} and Y_1, Y_2, \dots, Y_{n_Y} be, respectively, two independent random samples of sizes n_X and n_Y from the two normal distributions $N(\mu_X, \sigma_X^2)$ and $N(\mu_Y, \sigma_Y^2)$.

The distribution of $W = \overline{X} - \overline{Y}$ is

The confidence interval for $\mu_X - \mu_Y$ is

This also works when

The length of life of brand X light bulbs is assumed to be $N(\mu_X, 784)$.

The length of life of brand Y light bulbs is assumed to be $N(\mu_Y, 627)$ and independent of X.

If a random sample of $n_X = 56$ brand X light bulbs yielded a mean of $\overline{X} = 937.4$ hours and a random sample of size $n_Y = 57$ brand Y light bulbs yielded a mean of $\overline{Y} = 988.9$ hours,

find a 90% confidence interval for $\mu_X - \mu_Y$.

Suppose σ_X^2 and σ_Y^2 are unknown and the sample sizes are small. Assume that $\sigma_X^2 = \sigma_Y^2$.

Then,

$$T = \frac{Z}{\sqrt{U/(n_X + n_Y - 2)}}$$

has a student's *t* distribution of degree of freedom $n_X + n_Y - 2$ where

$$Z = \frac{\overline{X} - \overline{Y} - (\mu_X - \mu_Y)}{\sqrt{\sigma^2/n_X + \sigma^2/n_Y}}, \qquad U = \frac{(n_X - 1)S_X^2}{\sigma^2} + \frac{(n_Y - 1)S_Y^2}{\sigma^2}.$$

After simplification, T can be written as

Suppose that scores on a standardized test in mathematics taken by students from large and small high schools are $N(\mu_X, \sigma^2)$ and $N(\mu_Y, \sigma^2)$, respectively, where σ unknown.

If a random sample of $n_X = 9$ students from large high schools yielded $\overline{X} = 81.31$ and $S_X^2 = 60.76$, and a random sample of $n_Y = 15$ students from small high schools yielded $\overline{Y} = 78.61$ and $S_Y^2 = 48.24$.

Find a 95% confidence interval for $\mu_X - \mu_Y$.

Section 7.3. Confidence Intervals for Proportions

In a certain political campaign, one candidate has a poll taken at random among the voting population.

The results are that y = 185 out of n = 351 voters favor this candidate.

Should the candidate feel very confident of winning?

In general, suppose Y is a random sample from a binomial distribution with the given number of trials n and an unknown success probability p.

Note that Y/n is an unbiased point estimator for p and

$$\frac{(Y/n) - p}{\sqrt{p(1-p)/n}}$$

has an approximate normal distribution N(0, 1).

One-sided confidence intervals are sometimes appropriate for p.

For example, we may be interested in an upper bound on the proportion of defectives in manufacturing some item.

For an upper bound, we consider

$$\mathbb{P}\left(-z_{\alpha} \leq \frac{(Y/n) - p}{\sqrt{(Y/n)(1 - (Y/n))/n}}\right) \approx 1 - \alpha.$$

This gives

A lower bound is

One-sided confidence interval

Example

The Wisconsin Department of Natural Resources (DNR) wished to determine the prevalence, p, of chronic wasting disease (a neurological disease similar to mad cow disease) among its whitetail deer population.

In a particular area of the state, 272 deer were legally killed by hunters in a particular season. A tissue sample from each animal was submitted to the DNR.

Laboratory analysis determined that nine of the deer had chronic wasting disease.

Assume that the 272 harvested deer can, to a good approximation, be regarded as a random sample.

Find a one-sided approximate 95% confidence interval that provides an upper bound for p in that area of Wisconsin.

Suppose Y_1 and Y_2 are independent binomial random variables with n_1 , n_2 and p_1 , p_2 . To make a statistical inference about the difference $p_1 - p_2$, we consider $Y_1/n_1 - Y_2/n_2$.

Its mean is

Its variance is

So the CLT gives

Two detergents were tested for their ability to remove stains of a certain type.

An inspector judged the first one to be successful on 63 out of 91 independent trials and the second one to be successful on 42 out of 79 independent trials.

The respective relative frequencies of success are 0.692 and 0.532.

What is an approximate 90% confidence interval for the difference $p_1 - p_2$ of the two detergents?

A machine shop manufactures toggle levers.

A lever is flawed if a standard nut cannot be screwed onto the threads.

Let p equal the proportion of flawed toggle levers that the shop manufactures.

There were 24 flawed levers out of a sample of 642 that were selected randomly from the production line.

Find an approximate 95% confidence interval for p.
